

## Question # 42

Answer: A

$$d_x^{(2)} = q_x^{(2)} \times l_x^{(\tau)} = 400$$

$$d_x^{(1)} = 0.45(400) = 180$$

$$q_x'^{(2)} = \frac{d_x^{(2)}}{l_x^{(\tau)} - d_x^{(1)}} = \frac{400}{1000 - 180} = 0.488$$

$$p_x'^{(2)} = 1 - 0.488 = 0.512$$

Note: The UDD assumption was not critical except to have all deaths during the year so that 1000 - 180 lives are subject to decrement 2.
